

**Special Session title**

4th Special Session on Intelligent Public Transport

**Special Session proposer(s)**

Konstantinos Gkiotsalitis\*, Oded Cats, Konstantinos Kepaptsoglou

**Abstract**

Public transport plays a key role in maintaining sustainable mobility levels. Increased passenger demand and urbanization are expected to push public transportation operators to offer more reliable services and integrate their operations with micro-mobility options. Operations in public transportation systems are vulnerable to delays, disruptions, and other forms of uncertainty, such as the variation of passenger demand. Uncertainties related to traffic dynamics, operations, and passenger demand affect the reliability of the services and can lead to low passenger satisfaction and ridership loss. Although uncertainties are hard to predict, the influx of mobility-based data by intelligent sensors and real-time communication networks could be a game-changer. The availability of data from smartphones, traffic light sensors, APC/AFC/AVL, and MaaS applications has already impacted how both Civil Engineering and Computer Science tackle public transportation problems.

The availability of data enables a whole new bunch of possibilities which are far from being fully explored. For instance, public transportation planning that does not consider historical mobility-based data regarding the operational uncertainty offers services that perform well on the average case. However, they are vulnerable to disruptions which can affect the entire spectrum of the public transport system (e.g., the service frequencies, timetables, vehicle/crew schedules, and transfer synchronizations). This special session will investigate this area and provide answers to pressing research questions, such as:

- Which are the current trends in using smart data for public transport planning?
- How can we explore these data to improve public transportation?
- How can we improve the planning and control of public transportation given the newly available information?
- How can we improve the efficiency of preventive maintenance?

Being at a crossroads of data science and civil engineering, this special session intends to provide a platform to bring together data and civil engineering scientists working on public transport to build up together the next generation of reliable Urban Mobility.

**Keywords**

- Theory and Models for Optimization and Control
- Personalized Public Transit
- Public Transportation Management

### **Topics of interest**

- Delay propagation and prediction
- Measuring and quantifying reliability/robustness of public transportation systems
- Public transportation planning under uncertainty, e.g., reliable/robust line planning, frequency setting, timetabling, rolling stock / crew scheduling
- Intelligent real-time public transport control and operational management (bus bunching, stopskipping, vehicle holding, transfer coordination, corrective actions)
- Artificial public transportation systems and simulation
- Delay and disruption management
- Data-driven preventive maintenance policies
- Analysis of smartcard and mobility phone data
- Agent-based models for public transport systems
- Network theory applications in public transport
- Automatic assessment and evaluation of the public transport reliability
- Public transport scheduling in the era of Mobility-as-a-Service
